## **Module 3 Cheatsheet: JavaScript Programming for Web Applications**

Class or Method	Description	Example
appendChild()	An HTML DOM method that after creating an element, you can use this function to place the element in the appropriate location within the document. The element to append is the only parameter.	<pre>//Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>
Arrays	Created by declaring the array elements in []. An array can be assigned to a variable, usually using the keyword const or var. Arrays use zero based indexing to access their elements.	
Date()	Constructor is new Date([optional parameters]). If the constructor is declared with no parameters, it returns current local date and time. New dates can be created by passing parameters to new Date function.	<pre>//create a new date from a string var newDate = new Date("2021-1-17 13:15:30");  //create a new date instance representing 17 Jan 2021 00:00:00 //note that the month number is zero-based var newDate = new Date(2021, 0, 17);</pre>
<pre>document.createElement()</pre>	Takes one tag name parameter and creates an element with that name. Can place the element elsewhere on the page using functions like insertBefore(), appendChild(), replaceChild().	<pre>//Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>
<pre>document.createTextNode()</pre>	Takes a string as input text and returns a text node with the input text.	<pre><body onload="addPara()"> </body>  //Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head> <script> function addPara() {   var newPara = document.createElement("p");   var newText = document.createTextNode("Hello World!");   newPara.appendChild(newText);   document.body.appendChild(newPara); } </script> </head> <body onload="addPara()"> </body></pre>
<pre>document.getElementByID()</pre>	A method of the DOM that takes an ID value parameter and returns an element that matches the id.	<pre>//Changes the content of the div to "Hello World!" <div id="div1"></div></pre>
document.getElementsByTagName()	A method of the DOM that takes a tag name parameter and returns an array called "NodeList" that contains elements with the specified tag name.	<pre>//Gets an array of all elements in a document with the  tag. var tagNameArray = document.getElementsByTagName("p");</pre>
document.write()	Writes HTML or JavaScript to a document. Note that it overwrites any other text in the document so is mostly used for testing purposes only.	<pre>//Writes "Hello World" to the output stream. document.write("Hello World");</pre>
element.getAttribute()	Returns the value of the specified attribute. Takes one parameter: the attribute name whose value is to be returned.	<pre>//Removes the CSS style color blue <div id="div1" style="color: blue"></div> <script>   var div1 = document.getelementById("div1").getAttribute("style"); </script></pre>
element.innerHTML()	A property of the Element class that returns or alters contents of an HTML element as a text string.	<pre>//Changes the content of the div to "Hello World!" <div id="div1"></div></pre>

about:blank 1/3

7/7/24, 9:34 PM about:blank

```
//Removes the CSS style color blue
A property of the Element class that removes all previously <div id="div1" style="color: blue"></div>
                                                                                               <script>
                                     set inline CSS styles for a particular element. Takes one
element.removeAttribute()
                                                                                                var div1 =
                                     parameter: the attribute name that is being removed.
                                                                                               document.getelementById("div1").getAttribute("style");
                                                                                               </script>
                                     A property of the Element class that overwrites all
                                                                                               //In all elements named "the Image" sets the name of all src attributes to "another.gif" \,
                                     previously set inline CSS styles for a particular element.
element.setAttribute()
                                                                                               document.getElementById("theImage").setAttribute("src",
                                     Takes two parameters: the attribute name that is being set
                                                                                                'another.gif");
                                     and the attribute value the attribute is set to.
                                                                                               //Changes the CSS style color from blue to red
<div id="div1" style="color: blue"></div>
                                     A property of the Element class that returns or alters inline
                                                                                               <script>
element.style()
                                                                                                var div1 = document.getelementById("div1");
                                     CSS. Syntax is element.style.propertyName = value
                                                                                                div1.style.color = "red";
                                                                                               </script>
                                     Instance creates two properties about the error: message
                                                                                                //Catch statement defines a block of code to be executed
                                     that contains description of the error and the name property
                                                                                               if an error occurs in the try block.
                                     identifies the type of error. Generic error plus 6 other core
                                                                                               catch (err)
Error Objects
                                     errors: TypeError, RangeError, URIError, EvalError,
                                                                                                document.getElementById("myfile").innerHTML = err.name;
                                     ReferenceError, SyntaxError.
                                                                                               //Creates custom error message
throw new Error("Only values 1-10 are permitted");
                                     Error object can be extended to create custom error
                                     messages using the throw keyword.
                                     The history object is part of the window object and
                                     contains the URLs visited by the user within a browser
                                                                                               //Go back two pages if the history exists in the history
                                     window. It exposes useful methods and properties that let
History Objects
                                                                                               list.
                                     you navigate back and forth through the user's history and
                                                                                               history.go(-2);
                                     manipulate the contents of the history stack.
                                                                                               //Creates a new  element and places it in the
                                                                                               elementList before the first child of 
                                     An HTML DOM method that, after creating an element,
                                                                                               let newLI = document.createElement("li"):
                                     places a child element in the appropriate location before an
                                                                                               newLI.innerText = "new Element";
insertBefore()
                                     existing child. The method takes two parameters, the node
                                                                                               let elementList = document.getElementById("thisList");
                                     object to be inserted and the existing node to insert before.
                                                                                               elementList.insertBefore(newLI,
                                                                                               elementList.childNodes[0]);
                                                                                               //Returns the hostname property
let myhost = location.hostname;
newLI.innerText = "new Element";
                                     The location object is part of the window object and
Location Objects
                                     contains information about the current URL.
                                     The navigator object is part of the window object class in
                                     the DOM that represents the client Internet browser, also
                                                                                               //Retrieves the name of the browser
Navigator Objects
                                     called the user agent. There is no standard for this object so var browsername = navigator.appName;
                                     what it returns differs from browser to browser.
                                                                                               //Executes myFunction after MyHTMLPage has been loaded
                                                                                               document.getElementById("MyHTMLPage").onload = function ()
onload()
                                     A DOM event that starts a method when a page is loaded.
                                                                                               {myFunction};
                                                                                               //Creates a new node and replaces the second element in "thisList" with the word "blue"
                                     After creating an element, this function replaces a child
                                                                                               let secondBullet = document.createTextNode("blue");
replaceChild()
                                     node with a new node.
                                                                                               document.getElementById("thisList").childNodes[1];
                                                                                                                                        myList.childNodes[1]);
                                                                                               myList.replaceChild(secondBullet,
                                     The screen object is part of the window object class in the
                                                                                               //Returns the height and width of the user's screen
Screen Objects
                                     DOM that can be used to return properties about the user's
                                                                                               var height=screen.height;
                                                                                               var width=screen.width;
                                     screen.
                                     The DOM window object is at the top of the DOM
                                     hierarchy and serves as the global object. Everything in the //Opens a new browser window with the specified URL
Window Objects
                                     DOM takes place in a window. The window object
                                                                                               window.open("http://www.w3schools.com");
                                     controls the environment that contains the document.
                                     Opens a new window. The first parameter is a path, a URL,
                                     or an empty string, and optional parameters include the
                                     window name, features such as the placement of the
                                                                                               //Opens a new window that opens the IBM home page and has
                                     window or the dimensions, and a Boolean replace value.
                                                                                               a width of 600 and a height of 800)
                                     The feature parameter is a comma separated string of
window.open()
                                                                                               let thisWindow = window.open("http://www.ibm.com", "myWindow", "width"=600, "height"=800);
                                     name-value pairs and the replace parameter is an optional
                                     Boolean. This parameter has been deprecated so modern
                                     browsers may not support it. This method returns a
                                     reference to the new window object.
                                     Scrolls to a particular place in a window. Parameters
                                                                                               //Scrolls the window to the pixel located at the
window.scrollTo()
                                     include the x-coordinate which is the left-most pixel and
                                                                                               coordinate (20, 200)
                                                                                               window.scrollTo(20, 200);
                                     the y-coordinate which is the upper-most pixel.
                                                                                               //Enables the use of properties and methods of the String
                                                                                               class such as the property n.length
                                                                                               let n = new String ("abc");
                                     Primitive types can be converted to objects using wrapper
                                     objects. They are the same name as the primitive except
Wrapper Objects
                                                                                               //Returns string
                                     they start with uppercase letter. The typeof keyword
                                                                                               typeof "abc";
                                     returns a string indicating the data type of the operand.
                                                                                               //Returns object
                                                                                               typeof new String("abc");
